# Part I Preliminaries

## Chapter 1

## Relations and Functions

## Chapter 2

## The Integers and Modular Arithmetic

## Part II

Groups

### Chapter 3

### Introduction to Groups

#### 3.1 An Important Example

#### 3.1.1

In 
$$S_4$$
, let  $\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 3 & 1 & 4 & 2 \end{pmatrix}$ , and  $\tau = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 3 & 4 & 1 & 2 \end{pmatrix}$ . Calculate  $\sigma \tau$ ,  $\tau \sigma$  and  $\sigma^{-1}$ . 
$$\sigma \tau = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 4 & 2 & 3 & 1 \end{pmatrix}$$
$$\tau \sigma = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 1 & 3 & 2 & 4 \end{pmatrix}$$
$$\sigma^{-1} = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 4 & 1 & 3 \end{pmatrix}$$

#### 3.1.2

In 
$$S_5$$
, let  $\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 5 & 3 & 2 & 1 & 4 \end{pmatrix}$  and  $\tau = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 2 & 4 & 1 & 3 & 5 \end{pmatrix}$  calculate  $\sigma \tau \sigma$ ,  $\sigma \sigma \tau$ ,  $\sigma^{-1}$ .
$$\sigma \tau \sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 4 & 5 & 1 & 3 & 2 \end{pmatrix}$$

$$\sigma \sigma \tau = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 2 & 5 & 4 & 3 & 1 \end{pmatrix}$$

$$\sigma^{-1} = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 4 & 3 & 2 & 5 & 1 \end{pmatrix}$$

#### 3.1.3

How many permutations are there in  $S_n$ ? In  $S_5$ , how many permutations  $\alpha$  satisfy  $\alpha(2) = 2$ ?

We can follow that there are n! permutations total, and if we've got a restriction  $\alpha(2) = 2$ , then we've got (n-1)! permutation. For the case  $S_5$  it means that there are 4! = 24 such permutations.

#### 3.1.4

Let H be the set of all permutations  $\alpha \in S_5$  satisfying  $\alpha(2) = 2$ . Which of the properties of closure, associativity, identit, inverses does H enjoy under composition? All of them

#### 3.1.5

Consider the set of all functions from 6 to 6. Which of the ... Everything other then inverse

#### 3.1.6

Let G be the set of all ... All of them

#### 3.2 Groups

#### 3.2.1

Give group tables for following additive grops:  $Z_3$ ,  $Z_3 \times Z_2$ 

	0	1	2
0	0	1	2
1	1	2	0
2	2	0	1

last one is ommitted

#### 3.2.2

Give group tables for the following groups: U(12),  $S_3$ 

We follow that  $U(12) = \{1, 5, 7, 11\}$ . THus

	1	5	7	11
1	1	5	7	11
5	5	1	11	7
7	7	11	1	5
11	11	7	5	1

One of the programs in progs folder produces desired table for  $S_3$  (and can produce one for any  $S_n$  for that matter).

#### 3.2.3

Show that  $G \times H$  is abelian iff G and H are both abelian

Was proven in dummit and foote, check 1.1.29

Rest of the exercises in this section were either already proven in  $D \mathcal{E} F$ , are trivial, or could be solved at a later time if I encounter some gaps in the theory.

- 3.3
- 3.4
- 3.5

#### 3.6 Cyclic Groups

#### 3.6.1

Let  $G = \langle a \rangle$  be a cyclic group of order 12. List every subgroup of G. List every group of  $Z_{12}$ 

12's divisors are  $\{1, 2, 3, 4, 6, 12\}$ , therefore subgroups of G are  $\langle a^i \rangle$  for  $i \in \{0, 1, 2, 3, 4, 6\}$ Since  $Z_{12}$  is cyclic, we follow that  $\langle [0, 1, 2, 3, 4, 6] \rangle$  are the subgroups of  $Z_{12}$ .

#### 3.6.2

Let  $G = \langle a \rangle$  be a cyclic group of order 120. List all of the groups of order 120. List all of the elements of order 12 in G.

Divisors of 120 are  $\{1, 2, 3, 4, 5, 6, 8, 10, 12, 24, 60, 120\}$ , thus we can state that subgroups of a cyclic group are a to powers of those numbers

According to the theorems, there should be  $\phi(12) = 4$  elements of order 12. All of them lie in a subgroup  $\langle a^{120/12} \rangle = \langle a^{10} \rangle$  and are in form  $(a^{10})^k$  where  $k \in 1, 5, 7, 11$ .

How many element of order 12 are there in a cyclic group of order 1200?

Also 4.

#### 3.6.3

Let p be a prime and n a positive integer. Show that  $\phi(p^n) = p^n - p^{n-1}$ 

If  $j \in Z_+$  is such that j = pi for some  $i \in Z_+$ , then we follow that  $(p^n, j) = p$ , therefore they are not relatively prime. Suppose that  $(p^n, j) = 1$  for some  $j \in Z_+$ . Let S be a multiset of prime divisors of  $p^n N$  and T be a multiset of divisors of j. Then we follow that  $S \cap T = \emptyset$ , since otherwise we would've had that j is a multiple of p, which is not relatively prime to  $p^n$ . Thus we follow that the set of not relatively prime numbers to  $p^n$  is equal to the set of multiples of p.

We can follow that there are pricicely  $p^{n-1}$  of multiples of p that are less or equal to  $p^n$  (don't think that we need to prove that), therefore the total amount of numbers that are less or equal to  $p^n$ , which are relatively prime to  $p^n$  is  $p^n - p^{n-1}$ , as desired.

#### 3.6.4

Find all positive integers n such that |U(n)| = 24.

We can follow that  $\phi(n)$  is an function that tends to infinity (i.e. for every  $n \in Z_+$  there exists  $j \in Z_+$  such that m > n implies that  $\phi(m) > j$  since  $\phi(n)$  is larger than the number of prime numbers that is in the set  $Z_+ \cap [1, n)$ . Therefore we conclude that there is an upper bound for a number of numbers n such that  $\phi(n) = 24$ .

Brute-force shows that those numbers are

Can't come up with a better answer than that, but I'm sure that it's there.

#### 3.6.5

Let G be a nonabelian group. If H and K are cyclic subgroups of G, does it follow that  $H \cap K$  is also a cyclyc subgroup? Prove that it does, or provide a counterexample.

We follow that every subgroup has an identity in it, thus  $e \in H \cap K$ . Suppose that  $j \in H \cap K$ . We follow that  $j \in H \wedge j \in K$ . Since H and K are both subgroups, we follow that  $j^{-1} \in H \wedge j^{-1} \in K$ . Thus  $j^{-1} \in H \cap K$ . Therefore  $H \cap K$  is closed under inverses. We can follow also by the same logic that  $j, l \in H \cap K$  implies that  $jl \in H \cap K$ . Therefore we can conclude that  $H \cap K$  is a subgroup.

We can follow that if  $H \cap K = \{e\}$ , then it's cyclic. We can follow that  $H \cap K$  can be not only a trivial subgroup by setting H = K. Suppose that  $H \cap K \neq \{e\}$ . By the fact that both H and K are cyclic we follow that  $H \cap K = \{a^i : i \in \text{ some subset of } Z_+\}$ . Since  $H \cap K \neq \{e\}$ , we follow that there exists an element  $a \in G$  and two sets  $H', K' \in \mathcal{P}(Z_+)$  such that  $H = \{a^i : i \in H'\}$  and  $K = \{a^i : i \in K'\}$ . Since both H and K are cyclic we follow that

both H' and K' are the sets of multiples of some number. Thus  $H' \cap K'$  is a set of multiples of some number as well (proof ommitted). Thus we follow that  $H \cap K = \{a^i : i \in H' \cap K'\}$  is a cyclic group as well.

#### 3.6.6

Let  $G = \langle a \rangle$  be an infinite cyclic. If m and n are positive integers, find a generator for  $\langle a^m \rangle \cap \langle a^n \rangle$ .

We can follow pretty easily that  $\langle a^m \rangle \cap \langle a^n \rangle = \langle a^{lcm(m,n)} \rangle$
